

Fig. 1: Structures of Stress Perception

Structures of Stress Perception

- Thalamus rather for physical stressors
- Limbic system (a.o. hippicampus, amygdala, hypothalamus) together with the frontal lobe and the olfactory bulb rather for emotional stressors

Stress Reactions

Production of cytokines as e.g. tumor necrosis factor alpha (TNF- α), Interleukin-1 (IL-1), Interleukin 6 (IL-6)

- for fighting off infections and for other immune responses
- dysregulated and pathological in inflammation, trauma, and sepsis
- adverse effects of cytokines: linked to many disorders as e.g. schizophrenia, major depression and Alzheimer's disease or cancer

HPA axis

- Hypothalamus releasing
- -- the neuropeptide arginine vasopressin (AVP)
- -- the corticotropin releasing hormone (CRH)
- Anterior pituitary releasing adrenocorticotropic homone (ACTH)
- Adrenal cortex releasing glucocorticoids, adrenaline and noradrenaline

Autonomic nervous system (ANS)

Dominance of the sympathetic NS (fight or flight) over the parasympathetic NS (rest and digest)

Burnout Seminar: Stress Neurophysiology and Tips

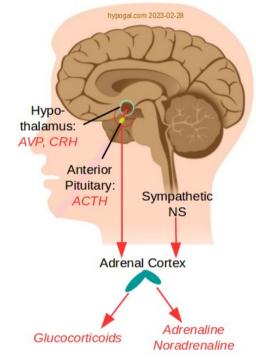

Fig. 2: Structures and Messengers of Stress Reactions

Possible Consequences of Chronic Stress

- Burnout syndrome (with the following symptoms)
- Sleep disorders (look at the next pages)
- Reduced physical perfomance and fatigue
- Metabolic dysfunction
- Immunodeficiency
- Pain syndrome
- Lack of concentration and memory problems
- Other mental problems

Chronic Stress Can Lead to Allostatic Load

Homeostasis: Maintain a balance in countless parameters; self-regulated by means of feedforward and feedback mechanisms.

Allostasis: Stability by means of change involving the adaptation to current and future challenges. Consequences of allostasis: damages such as wear and tear (allostatic load).

Allostasis can be needed to achieve homeostasis for more dominant parameters.

Factors provoking an allostatic load:

- Repeated hits: too frequent occurrence of stress reactions
- Lack of adaptation: no habituation to stressors
- Prolonged response: too long duration of stress reaction
- Inadequate response: too weak or too strong reaction to stressor

Treatments and Tips

Behavioral Changes

- Avoidance of stressors
- Better structured work
- Regular (short) breaks: between two patients or tasks
- Step by step, focusing on one task at a time
- Looking for joyful experiences

Physical Exercises

- Activation with pleasure, partly implemented in daily activities
- Cozy relaxation techniques
- conscious breaths at the window
- pursed lips breathing in the coachman's seat
- times for not thinking and not planning, but for being and feeling

Orthomolecular, Phyto- and Aromatherapy

- Vitamins: e.g. B12, C, E
- Minerals (magnesium) and trace elements
- Phytotherapy for sleep or stress disorders: e.g. ginseng, taiga root, rose root
- Calming scents: e.g. vanilla, cinnamon, jasmine

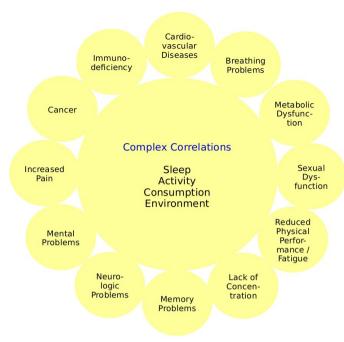

Fig. 1: Vicious Circles of many Parameters and Disorders

Sleep is important for regeneration and homeostasis. However, health depends on different parameters. There exist vicious circles influencing each other (Fig. 1). One of them includes sleep and mental health. Sleep disorders can be prodromal or aggravate mental disorders and vice versa.

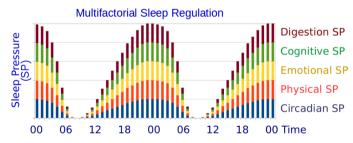

Fig. 2: Circadian Rhythm of Sleep Pressure

Sleep is impacted by many parameters (circadian, physical, emotional, cognitive, digestion). Sleep occurs when sleep pressure (SP, Fig. 2) is high enough. Some parameters are behavior controlled.

Burnout Seminar: Sleep

Disorders I: Neurophysiological

- Insomnia
- Sleep-related central breathing disorders
- Central nervous disorders with daytime sleepiness
- Circadian sleep-wake rhythm disorders
- Parasomnias
- Sleep-related movement disorders
- Restless-limbs syndrome
- Bruxism
- Sleep-related medical or neurological disorders

Physiotherapists can support patients to improve sleep quality and quantity.

Treatments I

The healthy lifestyle is fundamental.

Neurophysiological disorders are treated partly by cognitive behavior therapy for sleep disorders (CBT-S) including essential information e.g. on sleep hygiene (regular sleepwake rhythm, individual sleep duration, quietness, darkness, bed for sleep, sleep rituals, no clock).

Physiotherapists additionally can promote physical and cognitive activities, and relaxation skills (manually stimulated).

complexes are often not mentioned as sleep disorders; however, they are mostly related to sleep problems.

psychic), some

Diagnostic procedure: look at the next page.

More than a third of the population suffers

from sleep disorders. Many causes are

neurophysiological (and included in it

disorders have a **physical reason** (breathing obstructions or restrictions). **Other symptom**

sleep-related

breathing

Sleep Pathologies

Disorders II: Physical

- Obstructive and restrictive breathing disorders; e.g. obstructive sleep apnea (OSA)

Other Symptom Complexes

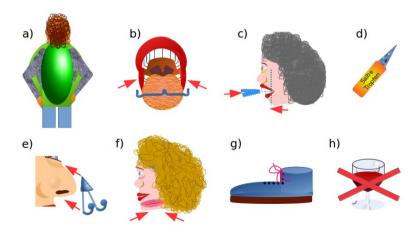

- Sleep and pain
- Sleep and tinnitus
- Hypothyroidism, hyperthyroidism

Treatments II

Physical disorders can be treated easiest by positioning, but also by some alternatives (Fig. 3).

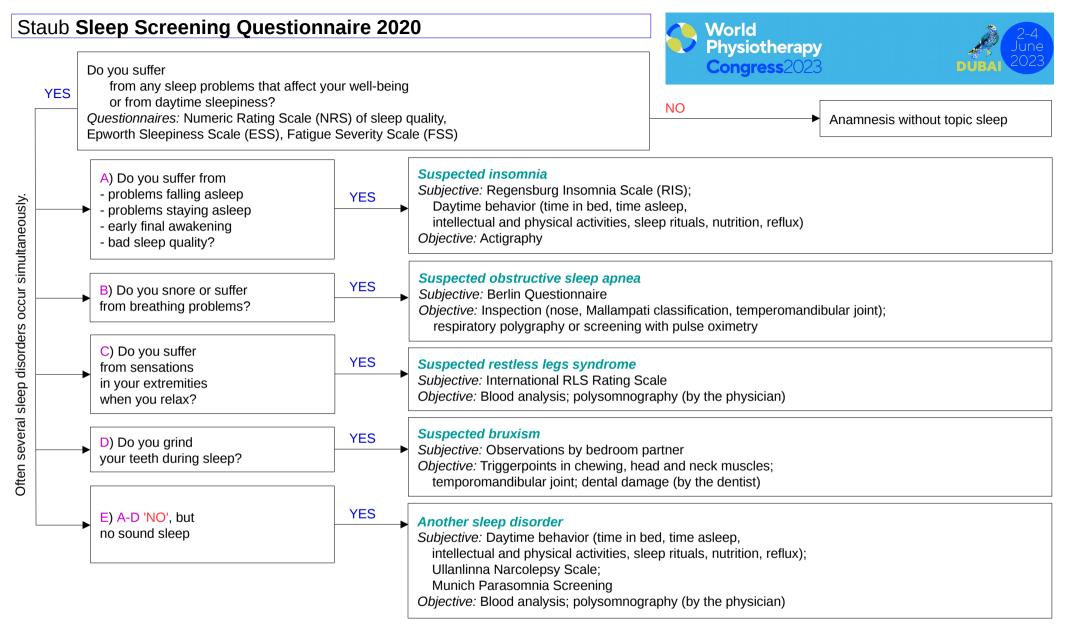

Physiotherapists work with evidence-based practice.

However, all symptoms must be treated in a holistic manner that is individually adapted to the situation and the patient.

a) Positional treatments (e.g. backpack) – b) Palatal device
c) Mandibular advancement device – d) Care of the nasal mucosa
e) Nasal dilator – f) Training (oropharyngeal muscles)
g) Weight reduction (endurance training, change in diet)
h) Consumption behavior (alcohol, smoking)

Evidence Based Medicine (EBM), neurophysiological explanations and assessments are crucial for the treatment success. EBM does not mean to have as many reviews as possible on a treatment option. And newer publications with the same results as older ones hardly lead to better therapeutic results, especially if the basics of pathology are not considered. In order to be able to adapt the treatment optimally to the individual in the actual situation, we must understand the neurophysiological explanations why a treatment can work but does not always work for every patient. E.g. negative associations with physical activity can reduce the positive effect of the exercises. In such cases, a different approach to the body can be helpful at the beginning. For EBM it is important that we measure the treatment success. Specific questionnaires and/or objective tests are always necessary to assess the severity of a disease. Procedures (practical work, studies) that do not take this into account are not worth much. – cristina-staub@sunrise.ch
